

Machine Learning Tutorial with scikit-learn

Sunglok Choi, Assistant Professor, Ph.D. Computer Science and Engineering Department, SEOULTECH sunglok@seoultech.ac.kr | https://mint-lab.github.io/

- Machine learning (shortly ML)
 - A sort of computer algorithms that achieve tasks (or models) automatically through the use of data
 - Data-driven approaches vs. rule-based approaches
 - <u>Induction</u> (귀납법 in Korean) vs. <u>deduction</u> (연역법 in Korean)
 - Artificial intelligence vs. machine learning vs. deep (neural network) learning

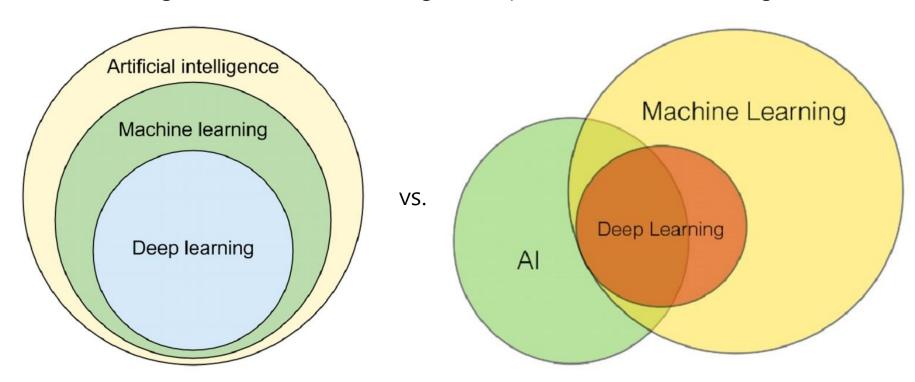

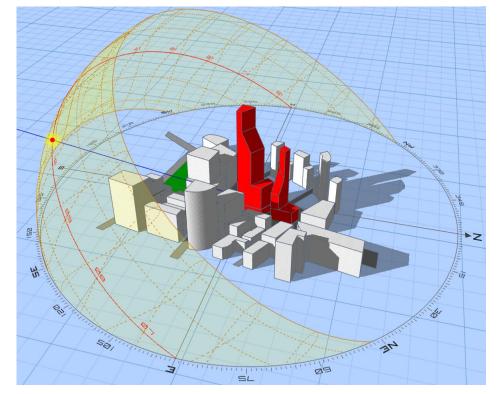

Image: Wikipedia

- Machine learning (shortly ML)
 - Data-driven approaches vs. rule-based approaches
 - Example) Selecting a parking spot while avoiding strong sunshine

VS.

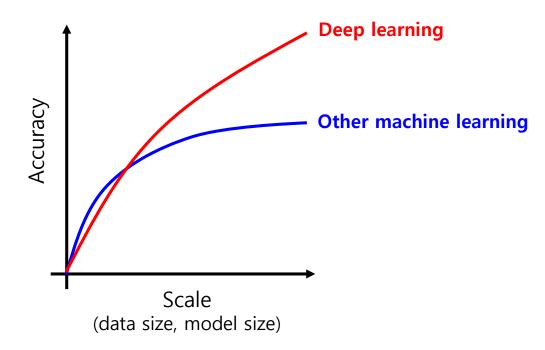

Data-driven approaches (shadow record)

Rule-based approaches (sun path, ray casting, ...)

Image: RealSpace, 3D Sun-Path

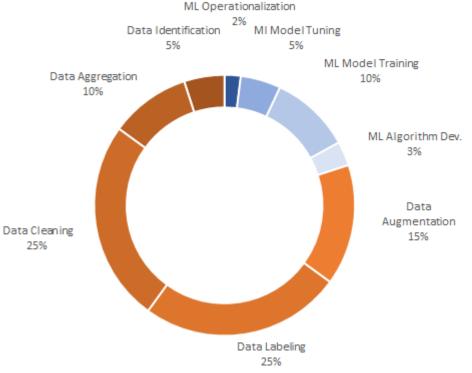

Why Machine Learning? (vs. Deep Learning)

ML procedure (~ trial and error)

80% of time spent for Machine Learning Projects is allocated to Data related tasks

- ML approaches (with respect to the given data)
 - <u>Supervised learning</u> (지도학습 in Korean): Given with <u>example inputs</u> and their desired <u>targets</u>
 - Note) Self-supervised learning, weakly supervised learning, semi-supervised learning, few-shot learning, ...
 - <u>Unsupervised learning</u> (비지도학습 in Korean): Given only with <u>example inputs</u> (without their targets)
 - Note) It was sometimes used for <u>feature learning</u> (a.k.a. representation learning).
 - <u>Reinforcement learning</u> (강화학습 in Korean): Given with <u>current input</u> and intermediate <u>feedback</u> (reward/penalty) after current action execution

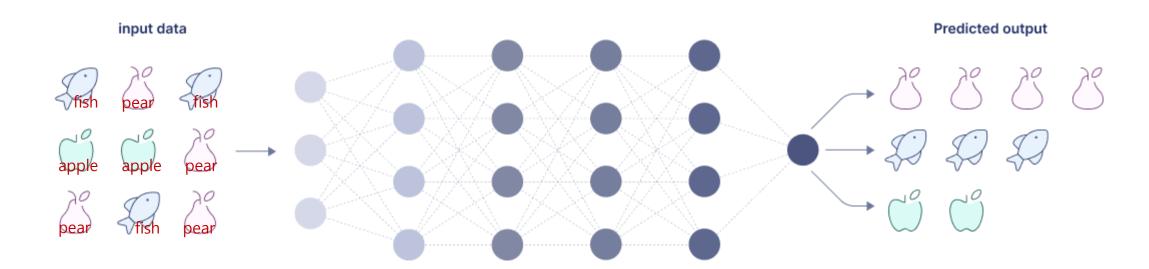

Image: Scribbr

- ML problem formulations (with respect to <u>the targets</u>)
 - <u>Classification</u>: Identifying which <u>category</u> (**discrete**) an observation belongs to
 - Regression: Finding parameters (continuous) well-associated with the given data
 - <u>Clustering</u>: Grouping similar data into <u>sets</u> (<u>discrete</u>)
 - <u>Dimensionality reduction</u>: Transforming the given high-dimensional data to their <u>low-dimensional representation</u>
 - Model selection: Choosing a model type and its parameters well-associated with the given data
 - Reinforcement learning: Finding an optimal policy for achieving a goal (more cumulative reward)

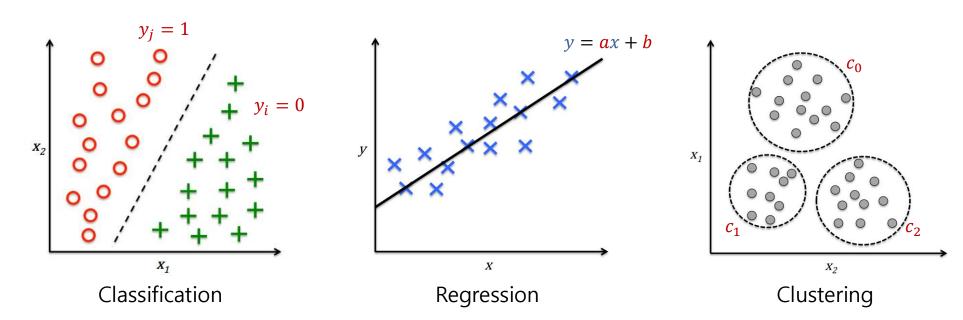

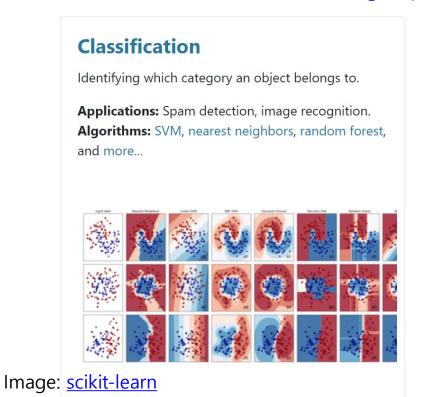

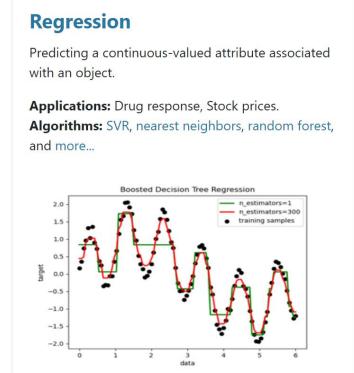

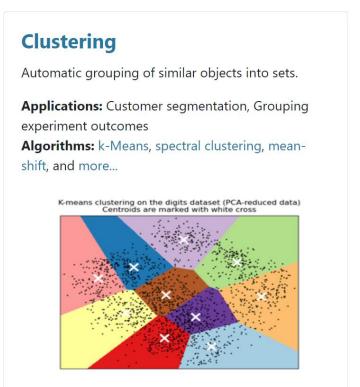

Image: Raschka's book

- <u>scikit-learn</u> (a.k.a. *sklearn*) is a Python-based open-source machine learning library.
 - It is built on NumPy, SciPy, and matplotlib (and included in <u>Anaconda</u> by default).
 - Its name sci stands for science.
- References (<u>Documentation</u>): <u>User guide</u> (~ ML book), <u>API reference</u>, <u>tutorials</u>, and <u>examples</u>
 - Example datasets for education and algorithm evaluation.
 - Note) <u>Machine Learning Repository</u>, UCI

Scikit-learn

Scikit-learn is an open source Python library that implements a range of machine learning, preprocessing, cross-validation and visualization learn algorithms using a unified interface.

A Basic Example

```
>>> from sklearn import neighbors, datasets, preprocessing
>>> from sklearn.model selection import train test split
>>> from sklearn.metrics import accuracy score
>>> iris = datasets.load_iris()
>>> X, y = iris.data[:, :2], iris.target
>>> X train, X test, y train, y test = train test split(X, y, random state=33)
>>> scaler - preprocessing.StandardScaler().fit(X train)
>>> X train - scaler.transform(X train)
>>> X test = scaler.transform(X test)
>>> knn = neighbors.KNeighborsClassifier(n neighbors=5)
>>> knn.fit(X train, y train)
>>> y pred = knn.predict(X test)
```

Loading The Data

>>> accuracy score(y test, y pred)

Also see NumPy & Pandas

Your data needs to be numeric and stored as NumPy arrays or SciPy sparse matrices. Other types that are convertible to numeric arrays, such as Pandas DataFrame, are also acceptable.

```
>>> import numpy as np
>>> X = np.random.random((10,5))
>>> X[X < 0.7] = 0
```

Training And Test Data

```
>>> from sklearn.model_selection import train_test_split
>>> X train, X test, y train, y test = train test split(X,
                                                 random state=0)
```

Create Your Model

Supervised Learning Estimators

Linear Regression

```
>>> from sklearn.linear model import LinearRegression
>>> lr = LinearRegression(normalize=True)
```

Support Vector Machines (SVM)

```
>>> from sklearn.svm import SVC
>>> svc = SVC(kernel='linear')
```

>>> from sklearn.naive bayes import GaussianNB >>> gnb = GaussianNB()

- >>> from sklearn import neighbors
- >>> knn = neighbors.KNeighborsClassifier(n neighbors=5)

Unsupervised Learning Estimators

Principal Component Analysis (PCA)

>>> from sklearn.decomposition import PCA >>> pca = PCA(n components=0.95)

K Means

>>> from sklearn.cluster import KMeans >>> k means = KMeans(n clusters=3, random state=0)

Model Fitting

Supervised learning

>>> lr.fit(X, y) >>> knn.fit(X train, y train) >>> svc.fit(X train, y train)

Unsupervised Learning

>>> k means.fit(X train) >>> pca model = pca.fit transform(X train) Fit to data.then transform it

Fit the model to the data

Prediction

Supervised Estimators

>> y_pred = svc.predict(np.random.random((2,5)) >> y pred = lr.predict(X test) >> y pred = knn.predict_proba(X_test)

Unsupervised Estimators

>> y pred = k means.predict(X test)

Predict labels Predict labels Estimate probability of a label

Fit the model to the data

Predict labels in clustering algos

Preprocessing The Data

Standardization

- >>> from sklearn.preprocessing import StandardScaler >>> scaler = StandardScaler().fit(X train)
- >>> standardized X = scaler.transform(X train) >>> standardized X test = scaler.transform(X test)

Normalization

>>> from sklearn.preprocessing import Normalizer >>> scaler = Normalizer().fit(X train) >>> normalized X = scaler.transform(X train) >>> normalized X test = scaler.transform(X test)

Binarization

>>> from sklearn.preprocessing import Binarizer >>> binarizer = Binarizer(threshold=0.0).fit(X) >>> binary X = binarizer.transform(X)

Encoding Categorical Features

- >>> from sklearn.preprocessing import LabelEncoder >>> enc = LabelEncoder()
- >>> y = enc.fit transform(y)

Imputing Missing Values

>>> poly.fit transform(X)

- >>> from sklearn.preprocessing import Imputer >>> imp = Imputer(missing values=0, strategy='mean', axis=0)
- >>> imp.fit transform(X train)

Generating Polynomial Features

>>> from sklearn.preprocessing import PolynomialFeatures >>> poly = PolynomialFeatures(5)

Classification Metrics

Accuracy Score

>>> knn.score(X_test, y_test) Estimator score method >>> from sklearn.metrics import accuracy score Metric scoring functions >>> accuracy_score(y_test, y_pred)

Classification Report

>>> from sklearn.metrics import classification report Precision, recall, fi-score >>> print(classification report(y test, y pred)) and support

Confusion Matrix

>>> from sklearn.metrics import confusion matrix >>> print(confusion_matrix(y_test, y_pred))

Evaluate Your Model's Performance

Regression Metrics

Mean Absolute Error

- >>> from sklearn.metrics import mean absolute error >>> y_true = [3, -0.5, 2]
- >>> mean_absolute_error(y_true, y_pred)

Mean Squared Error

>>> from sklearn.metrics import mean squared_error >>> mean_squared_error(y_test, y_pred)

>>> from sklearn.metrics import r2 score >>> r2 score(y true, y pred)

Clustering Metrics

Adjusted Rand Index

>>> from sklearn.metrics import adjusted rand score >>> adjusted_rand_score(y_true, y_pred)

Homogeneity

>>> from sklearn.metrics import homogeneity score >>> homogeneity_score(y_true, y_pred)

>>> from sklearn.metrics import v measure score >>> metrics.v measure score(y true, y pred)

Cross-Validation

>>> from sklearn.cross validation import cross val score >>> print(cross_val_score(knn, X_train, y_train, cv=4)) >>> print(cross val score(lr, X, y, cv=2))

Tune Your Model

Grid Search

>>> from sklearn.grid search import GridSearchCV >>> params = {"n neighbors": np.arange(1,3), "metric": ["euclidean", "cityblock"]} >>> grid = GridSearchCV(estimator=knn, param grid=params) >>> grid.fit(X train, y train) >>> print(grid.best_score_) >>> print(grid.best_estimator .n neighbors)

Randomized Parameter Optimization

```
>>> from sklearn.grid search import RandomizedSearchCV
>>> params = {"n_neighbors": range(1,5),
cv=4,
n iter=8,
                          random state=5)
>>> rsearch.fit(X_train, y_train)
>>> print(rsearch.best score )
```

DataCamp Learn Python for Data Science Interactively

- Iris flower dataset [UCI ML Repository] [scikit-learn] [API]
 - Classes (#: 3): <u>Iris setosa</u>, <u>Iris versicolor</u>, and <u>Iris virginica</u>
 - Attributes: 4 real numbers
 - Sepal length (unit: cm), sepal width (unit: cm)
 - Petal length (unit: cm), petal width (unit: cm)
 - Note) The values are quantized in the unit of 0.1 cm.
 - Note) In Korean, Iris 붓꽃, Sepal 꽃받침, and Petal 꽃잎
 - The number of data: **150** (50 for each class)
 - Example) Loading the *Iris* flower dataset
 from sklearn import datasets

```
iris = datasets.load_iris()

print(iris.target_names) # ['setosa' 'versicolor' 'virginica']
print(iris.feature_names) # ['sepal length (cm)', ...]
print(iris.data.shape) # (150, 4)
print(iris.target.shape) # (150,)
```

10

Image: Wikipedia

- How-to use (3 steps): Instantiation → training (fit) → inference/testing (predict)
- Example) Iris flower classification using support vector machine (SVM)
 - Accuracy with 4 attributes: **0.973** (146/150)
 - Accuracy with 2 attributes (sepal width and length): 0.820 (123/150)

```
import numpy as np
import matplotlib.pyplot as plt
from sklearn import (datasets, svm)
from matplotlib.lines import Line2D # For the custom legend
# Load a dataset
iris = datasets.load iris()
# Train a model
model = svm.SVC()
                          # Accuracy: 0.973 (146/150)
model.fit(iris.data, iris.target) # Try 'iris.data[:,0:2]' (Accuracy: 0.820)
# Test the model
predict = model.predict(iris.data) # Try 'iris.data[:,0:2]' (Accuracy: 0.820)
n correct = sum(predict == iris.target)
accuracy = n correct / len(iris.data)
```

Binary classification

- Classifying observations into one of two groups (1 or 0; True or False; positive or negative)
- e.g. Detecting spam e-mails
 (Determining whether an e-mail is *spam* or *normal*)
- Accuracy: # of correct answers / # of data
 - e.g. Accuracy of spam detection with 100 e-mails (spam: 10, normal: 90)

```
def is_spam_always_true(text):
    return True # Accuracy: 0.1 (10/100)

def is_spam_always_false(text):
    return False # Accuracy: 0.9 (90/100)
```

• Accuracy is not a good measure for imbalanced data (T: 10, F: 90).

Binary classification

Confusion matrix: 2D representation of correctness per classes

Predicted class

		+	_
class	P	TP true positive	FN false negative (type II error)
Actual	Z	FP false positive (type I error)	TN true negative

Note)
$$P = TP + FN$$

 $N = FP + TN$

$$ACC = \frac{TP + TN}{P + N}$$

$$BA = \frac{1}{2} \left(\frac{TP}{P} + \frac{TN}{N} \right)$$

ACC =
$$\frac{TP + TN}{P + N}$$

BA = $\frac{1}{2} \left(\frac{TP}{P} + \frac{TN}{N} \right)$

ative

$$RE = \frac{TP}{P} = \frac{TP}{TP + FN}$$

$$PR = \frac{TP}{TP + FP}$$

$$F1 = 2 \cdot \frac{RE \cdot PR}{RE + PR}$$

$$FPR = \frac{FP}{N} = \frac{FP}{FP + TN}$$

Accuracy

Balanced accuracy

Recall, hit rate, sensitivity, true positive rate

Precision, positive predictive rate

F1-measure

harmonic mean of precision and recall

$$FPR = \frac{FP}{N} = \frac{FP}{FP + TN}$$
 Fall-out*, false positive rate*

Note) higher* is worse.

Binary classification

Image: Wikipedia

Support vector machine (SVM) [scikit-learn] [API]

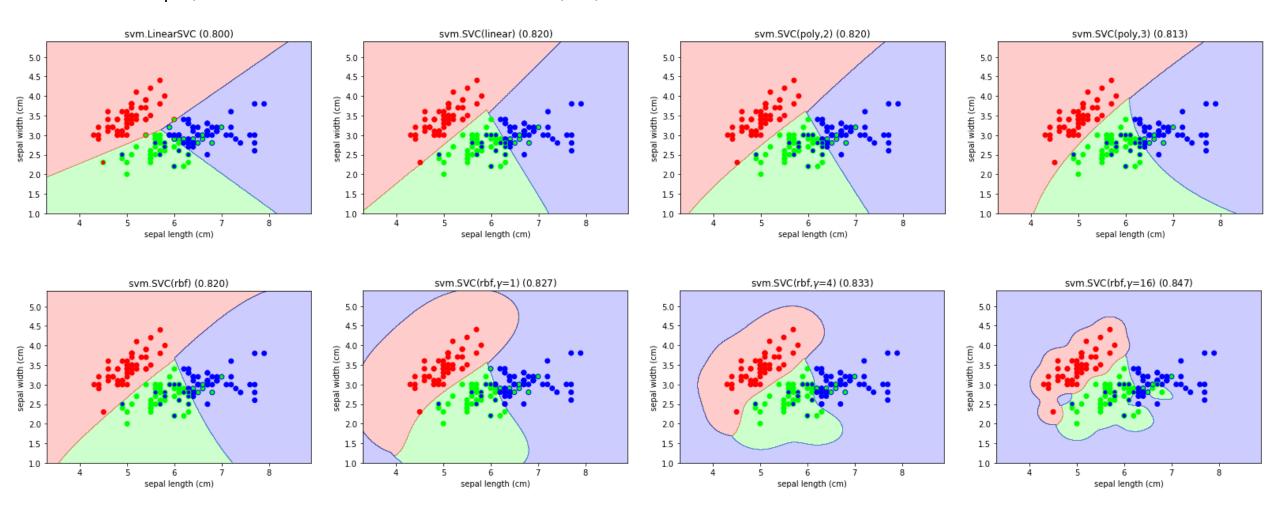

Kernel trick enables a non-linear classification.

- Advantages
 - Effective in high-dimensional spaces
 - Still effective in cases where # of dimensions > # of samples
 - Memory-efficient in training using a subset of data (called support vectors)
 - Customizable by specifying kernel functions
- Disadvantages
 - Does not directly provide probabilistic estimates
 - Often failed in highly noisy data and large-scale data

Image: Raschka's book

- Support vector machine (SVM) [scikit-learn] [API]

plt.show()
```

- Decision tree [scikit-learn] [API]
 - A <u>tree</u>-like model for decision with rules and outcomes (~ a if-then-else <u>flowchart</u>)
 - Advantages (due to a <u>white box</u>)
 - Simple to understand, interpret, and visualize
 - Easy to modify the trained tree
 - Easy to be combined with other decision methods
 - Disadvantages
 - Unstable and sensitive
 - A small change in the data can lead a large change in the structure of the optimal decision tree.
 - Easy to fall in overfitting
 - Discontinuous prediction
 - Relatively inaccurate
 - This disadvantage was improved by <u>random forest</u>, a ensemble of decision trees.

- Naïve Bayes classifiers [scikit-learn] [API]
 - A classifier based on Bayes' theorem under <u>Naïve assumption</u>

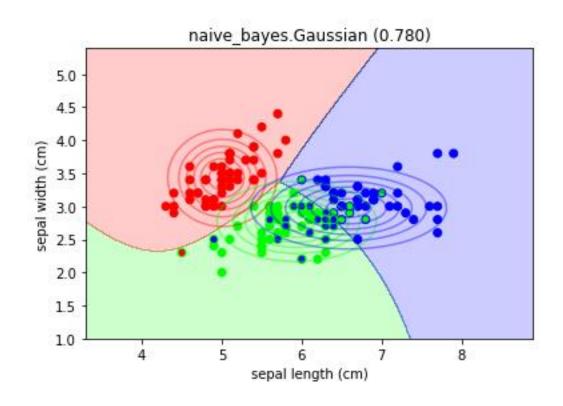

$$P(y|x_1,...,x_n) = \frac{P(y) P(x_1,...,x_n|y)}{P(x_1,...,x_n)} = \frac{P(y) \prod_{i=1}^n p(x_i|y)}{P(x_1,...,x_n)}$$

(posterior, likelihood, prior, and marginalization; y: class, x: data)

- Gaussian Naïve Bayes classifier if we assume $p(x|y) = \frac{1}{\sigma_y \sqrt{2\pi}} \exp\left(-\frac{1}{2} \left(\frac{x - \mu_y}{\sigma_y}\right)^2\right)$

	Discriminative model	Generative model
Goal	Directly estimate $P(y x)$	Estimate $P(x y)$, then deduce $P(y x)$
Trained	Decision boundaries	Probability distributions of the data
Illustration		
Examples	SVM, decision tree, regression, NN	Naïve Bayes, GMM, VAE, GAN

```

Regression

- Linear regression [scikit-learn] [API]
 - A linear modeling the relationship between a scalar response (y) and one or more observed variables (x_i)

$$y = b + a_1 x_1 + \dots + a_n x_n$$

- e.g. 2D line fitting: y = b + ax
- Example) Line fitting with scikit-learn (1/2)

```
Line: y=-0.663*x + 4.745 (score=0.961)
import numpy as np
import matplotlib.pyplot as plt
from sklearn import (linear model, metrics)
true line = lambda x: -2/3*x + 14/3
data range = np.array([-4, 12])
data num = 100
noise std = 0.5
# Generate the true data
                                                                       -2
x = np.random.uniform(data range[0], data range[1], size=data num)
y = true line(x) # y = -2/3*x + 10/3
# Add Gaussian noise
xn = x + np.random.normal(scale=noise std, size=x.shape)
yn = y + np.random.normal(scale=noise std, size=y.shape)
# Train a model
model = linear model.LinearRegression()
model.fit(xn.reshape(-1, 1), yn.reshape(-1, 1))
score = model.score(xn.reshape(-1, 1), yn.reshape(-1, 1))
# Plot the data and result
plt.title(f'Line: y={model.coef_[0][0]:.3f}*x + {model.intercept_[0]:.3f} (score={score:.3f})')
plt.plot(data_range, true_line(data_range), 'r-', label='The true line')
plt.plot(xn, yn, 'b.', label='Noisy data')
plt.plot(data_range, model.coef [0]*data_range + model.intercept, 'g-', label='Estimate')
plt.xlim(data range)
plt.legend()
plt.show()
```

The true line Noisy data

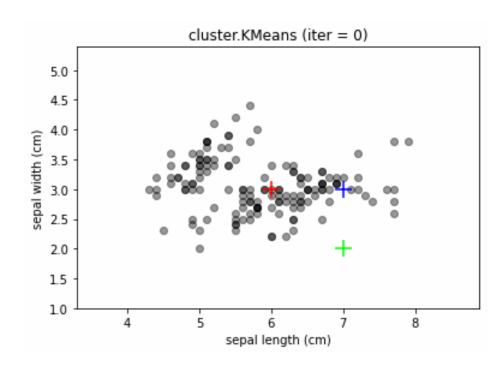

Estimate

Clustering

- <u>k-means clustering</u> [scikit-learn] [API]
 - k-means algorithm moves centroids that minimize the within-cluster sum of squares (WCSS; a.k.a. variance)
 - Initialization: Randomly select the initial centroids
 - Iterative update: Recalculate each centroid based on data with the previous membership

The *j*-th centroid:
$$\mu_j^{k+1} = \frac{\sum_{i=1}^n x_i \, \mathbf{1}(c_i = j)}{\sum_{i=1}^n \, \mathbf{1}(c_i = j)}$$
 where $c_i = \underset{j}{\operatorname{argmin}} \|x_i - \mu_j^k\|^2$

Example) k-means clustering with Iris flower dataset

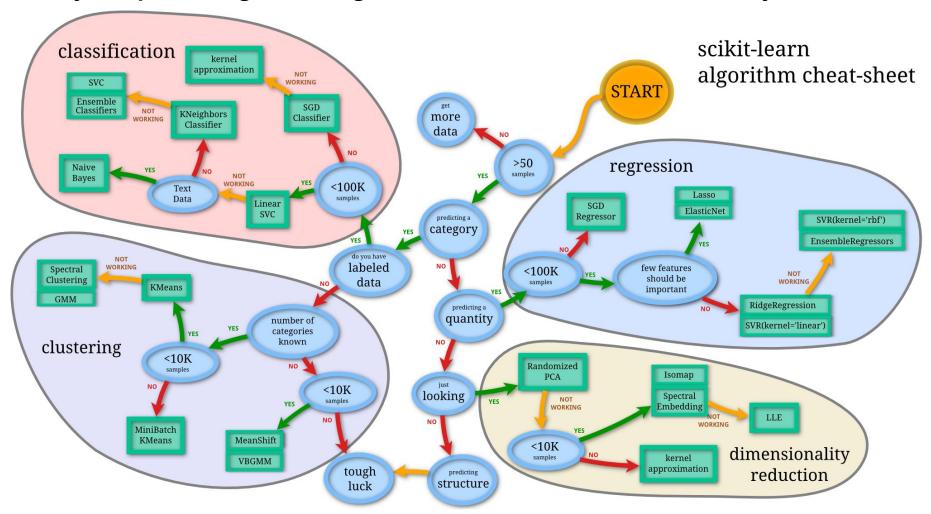

```
import numpy as np
                                                                                           cluster.KMeans (iter = 0)
import matplotlib.pyplot as plt
                                                                               5.0
from sklearn import (datasets, cluster)
                                                                               4.5
from matplotlib.colors import ListedColormap
                                                                             sebal width (cm) 3.5 3.0 2.5
# Load a dataset partially
iris = datasets.load iris()
iris.data = iris.data[:,0:2]
                                               # Try [:,2:4]
iris.feature_names = iris.feature_names[0:2] # Try [:,2:4]
                                                                               2.0
iris.color = np.array([(1, 0, 0), (0, 1, 0), (0, 0, 1)])
                                                                               1.5
# Train a model
                                                                               1.0
model = cluster.KMeans(n clusters=3)
                                                                                              sepal length (cm)
model.fit(iris.data)
# Visualize training results (decision boundaries)
x min, x max = iris.data[:, 0].min() - 1, iris.data[:, 0].max() + 1
y min, y max = iris.data[:, 1].min() - 1, iris.data[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, 0.01), np.arange(y_min, y_max, 0.01))
xy = np.vstack((xx.flatten(), yy.flatten())).T
zz = model.predict(xy)
plt.contourf(xx, yy, zz.reshape(xx.shape), cmap=ListedColormap(iris.color), alpha=0.2)
# Visualize testing results
plt.title('cluster.KMeans')
plt.scatter(iris.data[:,0], iris.data[:,1], c=iris.color[iris.target])
plt.xlabel(iris.feature names[0])
plt.ylabel(iris.feature names[1])
# Visualize training results (mean values)
for c in range(model.n clusters):
    plt.scatter(*model.cluster centers [c], marker='+', s=200, color='k')
plt.show()
```

Machine Learning FAQ

- Q) How to select a good ML algorithm or model?
- A) Mostly deep learning (if enough data are available), but not always

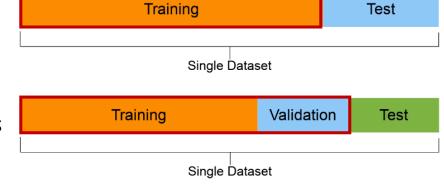

Machine Learning FAQ

- Q) How to get a good result (training)?
- A) More trials (more data/computing power), but your intuition and experience are important.
 - Good hyperparameter values?
 - <u>Grid search</u> (~ try all combinations) or your intuition/experience
 - Good model? Enough training?
 - Observing test results: <u>Underfitting</u> or <u>overfitting</u>

- Training, validation, and test data separation
 - Note) Validation data: Test data for intermediate trained models
- Enough data?
 - More is always good. Please think about the dimension of data and the number of model parameters.

Underfitting vs. Overfitting

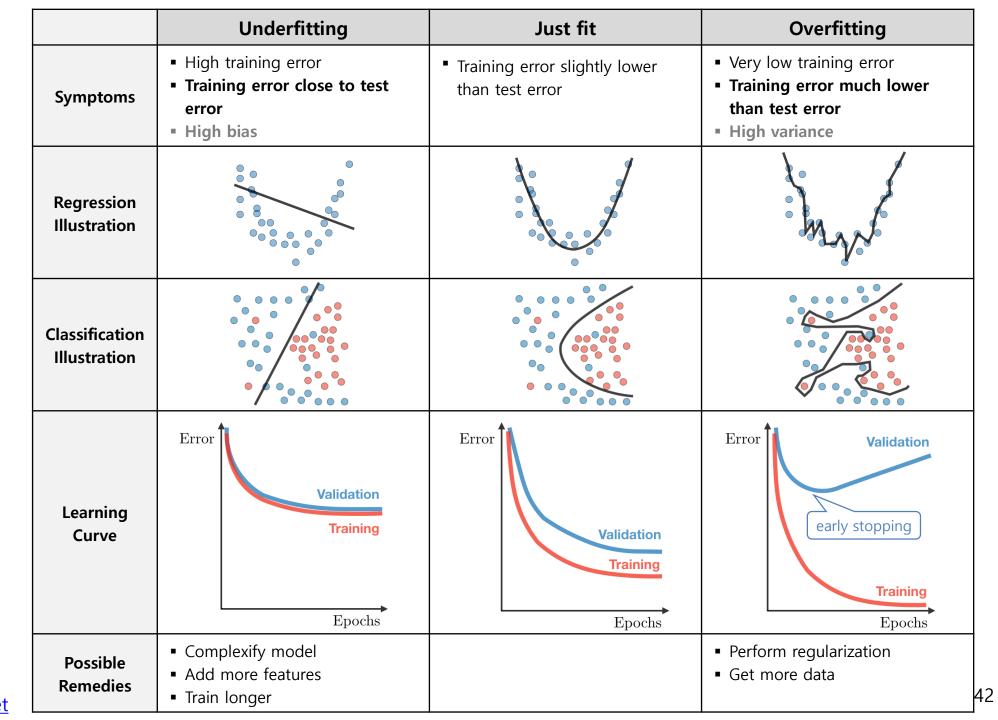

Image: Amidi's ML cheatsheet

Training, Validation, and Test Data Separation

- Holdout method: A simple training and test data separation
 - Holdout method separates training and test data in the given ratio (e.g. 7:3 or 9:1) and does not shuffle them.
 - Holdout method has danger to fall in overfitting to the fixed test data.
 - Example) Holdout validation with scikit-learn from sklearn import (datasets, svm, model selection, metrics) # Load a dataset iris = datasets.load_iris() iris.data = iris.data[:,0:2] iris.feature names = iris.feature names[0:2] X train, X test, y train, y test = model selection.train test_split(iris.data, iris.target, test_size=0.3) # Train a model model = svm.SVC() model.fit(X_train, y_train) # Evaluate the model acc_train = metrics.balanced_accuracy_score(y_train, model.predict(X_train)) acc_test = metrics.balanced_accuracy_score(y_test, model.predict(X_test)) print(f'* Accuracy @ training data: {acc train:.3f}') print(f'* Accuracy @ test data: {acc test:.3f}')

Training, Validation, and Test Data Separation

- Cross-validation (a.k.a. rotation estimation, out-of-sample testing)
 - Cross-validation is a sort of model validation <u>how the trained model will generalize</u> to an independent data set (e.g. unseen dataset from the real world).
 - It is common for academic researches.
 - It utilizes whole data more effectively for training and testing a model (compared to holdout method).
 - Exhaustive cross-validation
 - Leave-p-out cross-validation (LpOCV)
 - Training n p data and test p data for all possible combinations
 - C_p^n times of trainings (e.g. $C_{30}^{100} \approx 3 \times 10^{25})$ \rightarrow Usually not feasible
 - e.g. Leave-one-out cross-validation (LOOCV): n times of trainings (p=1)
- n = 8

 Test

 Train

 LOOCV

 Model 1

- Non-exhaustive cross-validation
 - k-fold cross-validation
 - LOOCV on k equal sized subsamples: k times of trainings

Machine Learning FAQ

Cross-validation

 Example) k-fold cross-validation with scikit-learn import numpy as np from sklearn import (datasets, svm, model selection) # Load a dataset iris = datasets.load iris() iris.data = iris.data[:,0:2] iris.feature names = iris.feature names[0:2] # Train a model model = svm.SVC() cv results = model selection.cross validate(model, iris.data, iris.target, cv=5, return train score=True) # Evaluate the model acc_train = np.mean(cv_results['train_score']) acc_test = np.mean(cv_results['test_score']) print(f'* Accuracy @ training data: {acc train:.3f}') print(f'* Accuracy @ test data: {acc test:.3f}')

Summary

Machine Learning

- Shortly data-driven approaches, inductive approaches
- Problem formulation: <u>Classification</u>, <u>regression</u>, <u>clustering</u>, ...

scikit-learn

Usage (3 steps): Instantiation → training (fit) → inference/testing (predict)

Classification

- Performance measures: accuracy, <u>confusion matrix</u> (balanced accuracy, <u>precision/recall</u>, F1-measure), <u>ROC curve</u>
- Support vector machine (SVM) [scikit-learn] [API]
- Decision tree [scikit-learn] [API]
- Naïve Bayes classifiers [scikit-learn] [API]
- Example) Iris flower data classification

Summary

Regression

- <u>Linear regression</u> [scikit-learn] [API]
- Example) Line fitting with scikit-learn

Clustering

- <u>k-means clustering</u> [scikit-learn] [API]
- Example) Iris flower data clustering

Machine Learning FAQ

- Good algorithm or model?
 - Mostly deep learning with (a ton of) trial-and-error
- Good model? Enough training?
 - Overfitting vs. underfitting
 - Data separation: <u>Train, validation, and test data</u>
 - Holdout method vs. Cross-validation
 - Early stopping
